Preterm is defined as a baby with a gestation of less than 37 completed weeks. Premature infants are known to be at risk of developing metabolic bone disease. Preterm have low serum Calcium and Phosphorus level, with increased serum alkaline phosphates activity. In this study serum Calcium, Phosphorus and ALP activities were measured in preterm babies. The present study comprised of 75 preterm babies of which 25 were of 28-30 weeks, 25 were of 30-32 weeks and remaining 25 were of 34-36 weeks (controls) of gestational age. Serum Calcium and Phosphorus levels were found to be significantly low and serum ALP activity were found to be significantly high (p<0.001) at 28-30 weeks as compared to 34-36 weeks (controls) but serum Calcium and Phosphorus levels were found to be insignificantly low while serum ALP activities were found to be insignificantly high at 28-30 weeks as compared to 30-32 weeks of gestational age in preterm babies. The correlation between serum Calcium and Phosphorus were found to be positive at all gestational ages whereas serum ALP is negatively correlated with serum Calcium and Phosphorus at all gestational ages. It can be concluded that high serum ALP activity and low serum Calcium, and Phosphorus levels are associated with preterm babies.

**INTRODUCTION**

Preterm is defined as a baby with a gestation of less than 37 completed weeks (that is, up to 36 weeks or less than 259 days) [1]. A "premature" infant is one that has not yet reached the level of fetal development that generally allows life outside the womb. In the normal human fetus, several organ systems mature between 34 and 37 weeks, and the fetus reaches adequate maturity by the end of this period [2].

Preterm birth is a high risk factor for perinatal morbidity, mortality and later on neurodevelopmental disabilities and adverse respiratory outcome [3]. Although, the rate of premature birth appears to vary by geographic region, the reported incidence varies between 6 and 10% [4]. Maternal medical conditions increase the risk of PB, and often labor has to be induced for medical reasons; such conditions include high blood pressure [5] pre-eclampsia [6] maternal diabetes [7] asthma, thyroid disease, and heart disease [8].

An increased risk of prematurity has been noticed among mothers who had a history of previous abortion and a history of previous twin pregnancy [9]. Worldwide,
Prematurity accounts for 10% of neonatal mortality, or around 500,000 deaths per year [10]. The incidence of preterm deliveries in India is 14.5% [11].

Premature infants are known to be at risk of developing metabolic bone disease (MBD) [12]. Metabolic bone disease is characterized by a failure of complete mineralization of osteoid and encompasses disturbances ranging from mild under mineralization (osteopenia) to severe bone disease with fractures (rickets). MBD is common (50–60%) in infants 28 wk of gestation and in those with birth weights 1000 g or less. In these infants, the cause is usually inadequate Ca and phosphate intake. The risk of MBD is inversely proportional to gestational age and birth weight, and directly related to postnatal complications.

Biochemical measurements of serum Ca, inorganic phosphate (Pi), and alkaline phosphatase (ALP) activity are used routinely to identify infants with MBD [13].

**MATERIALS AND METHODS**

For the present study 75 babies admitted to Department of Pediatrics and its neonatal unit was enrolled. The enrolled neonates were further divided into study group [50 neonates] and control group [25 neonates]. Fasting blood samples (12hr) were collected in EDTA vials & serum calcium, phosphorus and alkaline phosphatase were measured in three different groups of preterm babies at 28-30 weeks, 30-32 weeks and 34-36 weeks of GA.

Serum calcium was estimated by OCPC method. Serum phosphorus was estimated by Modified Metol method. Serum alkaline phosphatase was estimated by Kinetic p-NPP method.

Student-t test will be applied to calculate the significance in differences of these parameter between the groups. Regression analysis will be done to study the interrelation between the said parameters. All calculation will be done by SPSS 9 software.

**RESULTS AND DISCUSSION**

The present study was conducted in neonatal intensive care unit of Department of Pediatrics, Kamla Nehru Hospital in collaboration with Department of Biochemistry, Gandhi medical college, Bhopal, M. P. from January 2008 to January 2009.

Of the 75 preterm babies enrolled 45% were males & 30% females and there is 37 mothers of preterm babies were of a poor dietary intake, whereas 20 mothers were of an average dietary intake & 18 mothers were of a normal dietary intake.

The main findings of the study were:

1. Serum calcium & phosphorus levels were significantly low at 28-30 weeks as compared to 34-36 weeks (Controls), but it was insignificantly low at 28-30 weeks as compared to 30-32 weeks & at 30-32 weeks as compared to 34-36 weeks (Controls) of gestational age in preterm babies.
2. Serum alkaline phosphatase level was significantly high at 28-30 weeks & 30-32 weeks as compared to 34-36 weeks of gestational age in preterm babies but it was insignificantly high at 28-30 weeks as compared to 30-32 weeks in preterm babies.
3. The correlation between serum calcium & phosphorus were found to be positive at all gestational ages. The each of them increases with the advancement of GA in preterm babies.
4. Serum alkaline phosphatase is negatively correlated with serum calcium & phosphorus at all gestational ages. As the gestational age increased, the activity of serum alkaline phosphatase was found to significantly decrease in preterm babies.
5. Serum calcium & phosphorus level in preterm babies whose mothers were fed calcium & phosphorus rich diet was found to be significantly higher than that found in preterm babies whose mothers were not fed calcium & phosphorus rich diet.

**TABLE 1**

Table 1 shows comparison of serum calcium, phosphorus and serum alkaline phosphatase levels at 28-30 weeks & 34-36 weeks (Controls) of gestational age in preterm babies.

FIGURE 1
Figure 1 shows the trend of serum calcium and phosphorus in preterm babies

Decreased serum calcium & phosphorus levels in preterm babies signifies inadequate calcium & phosphate intake, reduced opportunity for transplacental mineral delivery & excessive mineral loss after birth in preterm babies, decreased bone mineralization & increased bone resorption, increased calcitonin & increased urinary calcium & phosphorus excretion in preterm babies. Increased alkaline phosphatase level signifies increased bone cellular or osteoblastic activity in preterm babies.

TABLE 4
Table 4 shows comparison of serum phosphorus levels in preterm babies whose mothers were fed & were not fed phosphorus rich diet (Milk, Cereals, Meat, Egg, Leafy Vegetables etc).

How to Submit Manuscripts

Since we use very fast review system, and since we are dedicated to publishing submitted articles with few weeks of submission, then the easiest and most reliable way of submitting a manuscript for publication in any of the journals from the publisher Research, Reviews and Publications (also known as Research | Reviews | Publications) is by sending an electronic copy of the well formatted manuscript as an email attachment to rrpjournals@gmail.com.

Submissions are often acknowledged within 6 to 24 hours of submission and the review process normally starts within few hours later, except in the rear cases where we are unable to find the appropriate reviewer on time.

Manuscripts are hardly rejected without first sending them for review, except in the cases where the manuscripts are poorly formatted and the author(s) have not followed the instructions for manuscript preparation which is available on the page of Instruction for Authors in website and can be accessed through http://www.rrpjournals.com/InstructionsForAuthors.html.

Research | Reviews | Publications and its journals have so many unique features such as rapid and quality publication of excellent articles, bilingual publication, some of which are available at http://www.rrpjournals.com/uniqueness.html.
